Warranty and Liability

1. If the licence disk or CD-ROM is defective POL will replace it at no charge provided the defective item is returned within thirty (30) days from the date of despatch from POL.
2. POL will refund the purchasing price provided all items (CD-ROM, licence disk and user manual) is returned within thirty (30) days from the date of despatch from POL and provided that all seals remain intact. No refund will be made if the seal has been broken on any items.
3. The latest version of POLTIPS-3 will be available to download from our web site.
4. POL will endeavour to contact all registered customers (preferably by e-mail) informing them that a new update has been placed on the web ready to download.
5. POL will provide technical support for POLTIPS-3 only to its registered users.
6. We do not guarantee that the functions contained in POLTIPS-3 will meet your requirements or that the operation of the program will be either error free or appear precisely as described in any documentation describing POLTIPS-3.
7. No responsibility can be accepted by NERC for any consequential loss or damage arising from any use that is made of POLTIPS-3 and output from POLTIPS-3 howsoever caused.
8. All implied warranties, terms, representations and conditions, including (by way of example only) the implied conditions of satisfactory quality and fitness for any purpose of the information, are excluded to the fullest extent permitted by law.
9. This Agreement is governed by English law and the parties submit to the exclusive jurisdiction of the English courts.

Introduction

The Proudman Oceanographic Laboratory

The Proudman Oceanographic Laboratory (POL) is a component laboratory of the UK's Natural Environment Research Council (NERC).

POL is based in Bidston on Merseyside at the old observatory. The new Proudman building was constructed in the mid-70s to house the rapid expansion of staff.

POL has provided a national and international tidal prediction service since 1924, in fact the modern methods of tidal prediction used throughout the world are based on the work of Dr. Arthur Doodson in the 1920s and who later became Director of the laboratory. Since then, POL has continued to develop and refine the analytical methods used to compute the tides. Coupled with advances in modern computer hardware and software, we now have the most accurate tidal prediction software available.

As the laboratory responsible for the installation, maintenance and running of the UK's National Tide Gauge Network we have access to the most accurate and up-to-date data which we utilise to derive harmonic constants used in the computation of tide tables.

Although some methods of tidal prediction use only a few harmonic constituents, the Proudman Oceanographic Laboratory uses up to 150 harmonic constants for some main ports, hence producing what POL believes to be the most accurate tidal predictions available.

The Applications Group

The Proudman Oceanographic Laboratory has, since the 1920s, had a team of tidal experts produce tide tables for organisations all over the world. In 1992, the group was renamed 'the Applications Group' and the range of data and services it offered was greatly expanded to include the results of the latest POL scientific research. However, oceanographic research tends to produce vast amounts of raw data with little meaning to anyone other than a trained oceanographer. The Applications Group

mission is to provide a 'value-added' service, which includes ensuring that the customer gets the data they require in a form that is easily understood. This is achieved by creating visualisations of the data, fully documented reports, or by processing the raw data to derive new data sets that are of more value to users in the 'real' world.

The Applications Group also develops software that allows users to buy raw data that remains hidden behind a friendly user interface, and carries out all the processing necessary to produce attractive and informative displays which can be easily printed or exported into other software.

POLTIPS-3 tidal predictions software

POLTIPS is one such product developed by the Applications Group. First released in 1993 as a DOS product for PCs, its success has led to successive refinements, and the inevitable move to the Windows™ environment.

The third and latest version of POLTIPS is by far the most powerful and user friendly version to date. Hidden behind the simple to use interface is a powerful mathematical engine for computing the tides, combined with sophisticated graphical layout tools for producing tide tables and graphs of the tide. Combined with POL's internationally renowned reputation for accuracy, POLTIPS is one of the most powerful tidal prediction programs available.

What's New in Version 3

- Improved user interface
- Improved map display with simple scrolling and zooming
- High water only or low water only predictions
- Instant next 7 days, this month or this year predictions
- Improved standard tide table display
- Hourly height tide table format
- Custom tide table layouts to create your own unique look
- Save predictions as text files to disk
- Copy unlimited size predictions to the clipboard
- Use POLTIPS with your own harmonic constants (customised and UserData licence only)
- Tidal statistics for locations
- Formatting for the standard list output
- Select metres or feet as your preferred unit
- Select accuracy of 1,2 or 3 decimal places
- Latest data sets for the most accurate predictions

What are the differences between the Standard, Customised and UserData versions of POLTIPS

Due to the different requirements of the wide variety of POLTIPS users, we have created three different versions of POLTIPS-3. They are basically the same program but have certain restrictions imposed.

The **standard version** can be bought with either a three or five year licence and contains around 700 UK ports. This has a slightly reduced accuracy over both the POL in-house predictions and the Customised version of POLTIPS-3. Users of the standard version are **not** licensed to publish the data in any form (including on the Internet) however the tide tables can be distributed free of charge within a membership club (e.g. a sailing or fishing club). Users cannot use the custom tide-table layouts or their own harmonic constants with the software.

Although the accuracy is slightly reduced compared with the customised version, it is still suitable for the majority of applications. For consultancy or engineering use, we recommend the customised version.

The **customised version** of POLTIPS-3 is purchased on an individual port basis with either a two or three year licence. Users are permitted to publish the tide tables for resale in any number of books for which they own the complete copyright (i.e. users **cannot** purchase this software and then sell the results on to third party publishers without written permission from POL). See also the restrictions on Internet publishing below. Users will also be able to use the custom tide table layout and use their own harmonic constants (subject to the same 2 or 3-year licence).

The **UserData version** of POLTIPS-3 is provided without any data sets. It is for use by users who want to compute predictions using their own harmonic constants and is usually sold with a 10 year licence.

Publishing tidal prediction on the Internet

Only users of the customised and UserData version of POLTIPS-3 can publish the results on the Internet. **This is limited to one month in advance of the current date.**

Hardware Requirements

The minimum requirements for POLTIPS-3 is a PC running Windows 95, 98, NT4, ME or 2000 (**not** Windows 3.1x) with about 5MB of free hard disk space. The recommended minimum is 200MHz Pentium with 32MB or more of memory.

Prediction Methods

Harmonic constants are used for computing predictions for standard ports with time and height differences used for the secondary ports. Some standard ports have additional tidal terms called Shallow Water Corrections.

Harmonic Constants and Standard Ports

A set of harmonic constants exists for most of the main ports around the coast. These are called **standard ports**, and POLTIPS•3 can compute equal interval predictions as well as high and low waters. Sets of harmonic constants usually exist only for locations where there has been a tide gauge and a suitable period of observed data to analyse (for example, ports on the National Tide Gauge Network, or locations of particular scientific interest).

A few standard ports have quite a complex tidal pattern that cannot be accurately reproduced just using harmonic constants. These ports have additional factors called shallow water corrections, used to make small adjustments to the high and low water times and heights.

Equal interval predictions cannot be made for ports with shallow water corrections.

Secondary Ports

There are many locations around the coast where long periods of tidal observations do not exist. Predictions for such locations are computed by making a prediction for a nearby main port, and then applying time and height differences to the high and low waters. Each secondary port has 4 separate time differences depending on whether high or low waters are being predicted and on the time of day. There are also 4 height differences for mean high and low water springs and neaps.

Equal interval predictions cannot be computed for secondary ports.

Conventions used in this manual

File  **Print** means from the 'File' menu, select 'Print'.

abcdefg means you type this text in.

 + X means hold down the shift key and press 'X'.

 + X means hold down the control (or ctrl) key and press 'X'.

Installing and starting POLTIPS•3

How to install POLTIPS•3

Please read before installation

Before installing POLTIPS•3 on your system, please ensure that you have the CD **and** the licence floppy disk. If either is missing, contact the Proudman Oceanographic Laboratory.

Insert the POLTIPS•3 CD into your CD-ROM drive. The CD should automatically run the installation program. If this does not start after 20 seconds, you will need to run the program manually as explained below.

Click on  and select **Run**. In the dialog box, type

d:\setup

where **d** is the drive letter of your CD-ROM, and click OK. Follow the on-screen instructions. Part way through, you will be asked to insert the floppy disk containing the licence into your floppy disk drive.

When the installation program asks for a destination folder to install POLTIPS into, accept the default folder otherwise the automatic licence and font installation will not work.

POLTIPS•3 will be installed on your computer's hard disk (the default location is **c:\Program Files\POLTIPS-3**) and an icon will be created automatically on the programs menu of your Start Button and on your desktop.

Manual installation of moons phases font

The moon symbols font should install automatically provided you have installed POLTIPS into the default location, and your Windows folder is either **c:\windows** or **c:\winnt**. If the font did not install, you can install it manually by copying the **moonsym.ttf** file from the floppy disk into the fonts folder inside your windows folder.

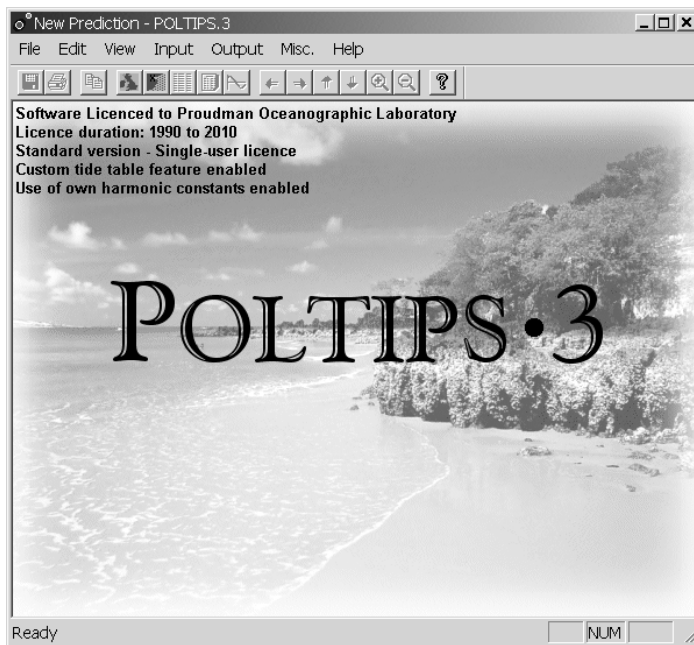

How to start POLTIPS•3

To start POLTIPS•3, click on the start button, select **Programs** and then **Poltips3**. Alternatively, double-click the icon on your desktop.

Ports with complex tidal patterns

Some ports have unusual tidal characteristics (e.g. Bournemouth, Cowes, Poole, Portland, Southampton and Weymouth). If you use POLTIPS•3 to do predictions for any of the above ports, please read the section “Locations with unusual tidal characteristics” on page 17.

The POLTIPS•3 Window

The picture above shows how the POLTIPS•3 should first look when you start the program. Interaction with the program is done through the options on the program menu, however, more commonly used controls have a button on the toolbar to provide quicker access.

This screen also gives information on your licence and restrictions on the use of the software. The first line gives the company name the software is licensed to. Do not give copies of the software to other people, as it will have your company name embedded within the software.

The licence duration is the period for which predictions can be made. Note that the software can be used outside of this period, but it will only make calculations for the years specified.

The third line specifies whether you have a standard, customised or UserData licence (see page 7), and whether this is a single-user licence or a network licence.

The last two lines specify whether the custom tide table feature is enabled (see page 31), and whether you are licensed to use your own sets of harmonic constants with the software (see page 37).

Toolbar

The buttons on the toolbar are:

save the prediction to a text file on the disk

print the display currently on screen

copy the prediction data to the clipboard

display the map

set the input parameters for the prediction

display the prediction in list format

display the prediction as a tide table

display the prediction as a graph

scroll and zoom buttons

about POLTIPS•3.

Using POLTIPS•3

This section takes you through what you need to know to produce your first printed tide table.

Setting the parameters for the prediction

Before you can compute the tides, you need to tell POLTIPS•3 where you would like the tide table for, the duration of the tide table and the type of prediction. Select **Input** → **Tidal Predictions...** to bring up the dialog box shown below.

Tidal Predictions

7 days This Month This Year

Type of prediction

☒ High and low waters

☐ Equal interval 60 mins

☐ High waters only

☐ Low waters only

☐ Statistics

Compute Cancel Show on map

☐ Adjust for British Summer Time (BST)

First select the port you require from the list of ports. You can either scroll down the list using the arrows and scroll bar, or just start typing the name in the box and the list will scroll automatically to the right place. Once you see the port name in the list, click on it.

Now set the start and end date of the prediction you require in the date boxes – either by typing in the number directly, or using the up and down arrows next to each box.

Alternatively, just click on one of the three preset buttons to make a prediction for the next 7 days, the current month or the current year. The dates will be filled in automatically for you.

Then select the type of prediction you require from the choice of five types. The default is to compute high and low waters (sometimes known as turning points), however you can select equal interval predictions and

specify the time interval in minutes (default is 60 minutes). You can also opt to just have the high waters, the low waters or general tidal statistics for the location (see page 21).

Finally select if you want times adjusted for British Summer Time (box ticked) or to leave all times in GMT/UT (unticked).

And that's it ... just click '**compute**' and the results will be displayed in the window. If you selected a long duration or you have a slower computer, you will see a progress indicator in the bottom left corner of the window and the calculation may take a few seconds.

04/01/2001	07:00	3.69
04/01/2001	13:30	10.20

Prediction completed

When you make a prediction, it is always initially displayed in what is called the list view (see picture). This gives one high water or low water per line. As high waters and low waters always alternate (unless you selected "high waters only" or "low waters only" in the dialog box) it should be obvious which is a high water and which is a low water.

To scroll up and down through the prediction, use either the page up and down keys on your keyboard, the up and down cursor keys or the up and down arrows on the toolbar.

At any time you can switch back to the list view from one of the other views using **Output** → **List View** or clicking the toolbar button 

If you save a prediction to disk, or copy it to the clipboard, it is the list format that is used (even if you are viewing another format on screen).

You can also choose to print the data in this format, however for any duration longer than a week or two, it would generate quite a few pages of output. A more sensible format for printing is the tide table format.

Tide table view

The tide table view outputs the prediction in a more traditional tide table layout as shown below, and is selected with **Output** > **Tide Table** or clicking on the tide table toolbar button .

In the illustration above, the window has been resized to make the text clearer. The tide table pages is always sized to fill the width of the window, however because the window is not usually the same shape as a piece of paper, you will not be able to see all the tide table at once.

You can scroll up and down to see the rest of the page using the up and down arrows on the keyboard or the toolbar. To move onto the next page of the tide table, use the left and right arrows or page up and page down on the keyboard.

To print the tide table, select **File** > **Print** or click the print button on the toolbar. From the print dialog you can select which pages of the tide table you wish to print and the number of copies, as well as being able to change all the settings specific to your printer.

Why do some days only have three tides?

The average time between successive turning points is 6 hours and 12½ minutes (i.e. four tides take 24 hours and 50 minutes meaning the tide moves on by 50 minutes each day). About every 7th or 8th day, one of the tides moves across midnight into the next day leaving only three turning points on that day.

Why is the phase of the moon shown on a tide table?

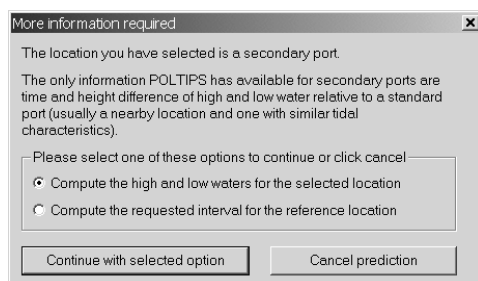

The tide is directly related to the phase of the moon. Spring tides usually occur 1 to 2 days after new and full moon and neap tides 1 to 2 days after the first and third quarter. The moon symbols are shown to enable easy identification of springs and neaps.

A = New Moon B = First Quarter C = Full Moon D = Third Quarter

Equal Interval Predictions

An equal interval prediction is one that gives the height of the tide at certain equally spaced time intervals (for example every 15 minutes or every hour), rather than at the specific time of high and low water. Using this type of prediction you can see how the tide changes over time.

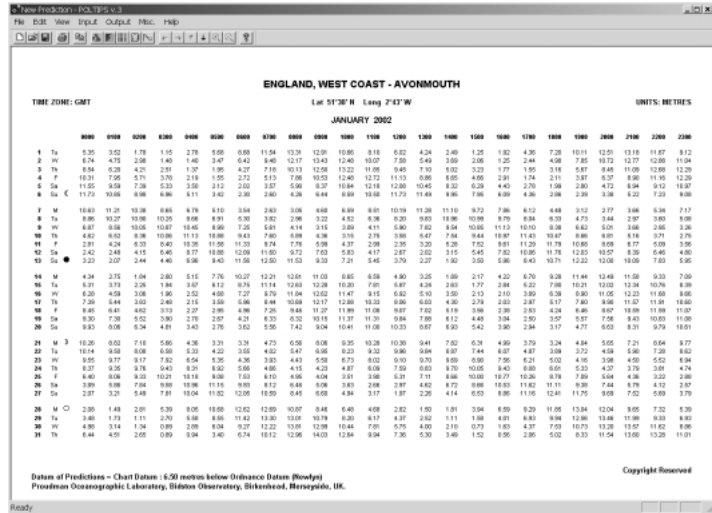

Equal interval predictions are only available for standard ports, not secondary ports (see page 8). If you ask POLTIPS-3 to compute an equal interval for a secondary port, you will be asked whether you would like to use the reference standard port, or whether you would like to change to high and low waters for your selected port. Select the option you require to continue, or cancel the prediction.

The list view for equal interval predictions is the same as for high and low waters, however the time intervals are equally spaced.

The tide table view for equal interval predictions is completely different from the high and low water tide table and is available only when the interval is set to 60 minutes – this is often called an hourly height table.

Note that all times for equal interval predictions are given in GMT/UT only – British Summer Time (BST) is not supported.

As with the high and low water tide table, the full width of the window is used meaning that you may need to scroll up and down with the arrow keys or toolbar buttons to see the whole table.

When printing the hourly height tide table you must set the printer to landscape mode rather than portrait. If you forget to change this, you will get a warning message appear and printing will not continue until this has been changed.

Locations with unusual tidal characteristics

Some ports experience unusual tidal patterns such as double high waters (e.g. Southampton) or double low waters (e.g. Portland or Weymouth). When POLTIPS•3 computes the high and low waters for such a port, it may find that there are more than four turning points in any one day. If this is the case the program will display the following dialog box.

If 'Yes' is selected, POLTIPS•3 will decide which are the primary high and low waters for the prediction and remove the extra ones. If all the turning

points are required, then select 'No' and all the turning points will be displayed.

Note that the tide table view cannot display more than 4 tides per day so you will only see the first four tides on each day.

Warning : If you decide to remove the extra turning points, a series of rules are used to try and identify which are the main high and low waters. These rules will work more reliably if the prediction is for a period of at least 21 days. However POLTIPS•3 can still get it wrong for some locations which have a very complex tidal pattern (e.g. Poole, Weymouth), and it is advisable to check that the correct tides have been removed by looking at a graph.

The illustration above shows an example of when POLTIPS•3 has identified the first high water as the significant one, but a few days later, the second high water has become the more significant one. At one point, on the 19th January, there is even a third high water.

To manually check to see if POLTIPS•3 has removed the correct tides, you should print out the results with the extra tides removed and compare them to a prediction with all the tides. Alternatively, compare the turning points to a graph of a prediction made at a 10 minute interval for the same period.

Output precision and units

The output precision on the list view and the tide table view can be set to 1, 2 or 3 decimal places (the default being 2). Note that although the data can be output to 3 decimal places, it does not imply that the data is accurate to 3 decimal places as there are many factors that can influence the tides (see Time and Tide on page 41). To change the precision of the output, select **Output** ↗ **Precision**.

You also have the option of switching the units used for the sea level between metres (default) or feet. Select **Output** ↗ **Units** and select the unit you require.

Note: if you select feet for the units, the value is a decimal value and not feet and inches (e.g. 4.5 means 4½' (4'6") and not 4'5").

Datums

What is a Datum

When measuring the height of something, you must specify what that height is measured relative to. For example if you hold a ball out in front of you over a desk, the height of the ball is say 70cm above the desk. However if someone comes and takes the desk away, you could say the height of the ball is 145cm above the floor. You have two different heights even though you have not moved your arm. What has happened is that the datum has changed. In the first case the datum was the desk, and in the second, the datum was the floor.

Likewise tide heights must be measured to a specified datum – the two most common being Chart Datum and Ordnance Datum, although some ports use a datum specific to that location (for example a dock sill). These are called special datums.

Chart Datum

This is the most common datum used on tide tables and is defined as the datum of soundings on Admiralty Charts. It is usually set to correspond to the lowest level to which a tide can fall under normal conditions (called the Lowest Astronomical Tide or LAT), therefore making all the predicted tide level values positive. However this is not always the case and for some ports, the surveying authority has set chart datum above LAT.

Chart Datum does not conform to any uniform tidal level as it is based on the tidal range at the location. Therefore it is not a suitable datum for comparing levels at more than one location.

Ordnance Datum

Ordnance datum is sometimes referred to as land survey datum, and is a horizontal plane. It is used when the absolute heights along a stretch of coastline need to be compared. The datum used for the British mainland (and some of the closer offshore islands) is called Ordnance Datum (Newlyn) as it is based on the average value of mean sea level at Newlyn for the six year period from 1915 to 1921. Due to the subsequent rise in mean sea level, this datum is now about 0.2m below mean sea level at Newlyn.

For locations not on the British mainland, other horizontal datums exist – Ordnance Datum (Belfast) [ODB] for Northern Ireland, Ordnance Datum (Dublin) [ODD] for the Republic of Ireland and Ordnance Datum (local) [ODL] for more remote locations. European locations have their own land-levelling datum.

Datums in POLTIPS•3

When making a prediction in POLTIPS•3, the default datum is always Chart Datum unless a special datum is specified for the port (usually given in the port name). For most locations, you can switch between Chart and Ordnance datum by selecting **Output > Datum** and choosing the one you require.

The currently selected datum is displayed on both the list view and the tide table view.

Formatting the List View

One of the main uses of the list view is for getting the tide data into another Windows application (such as Microsoft Excel spreadsheet). To allow for more flexibility, POLTIPS•3 will let you change some aspects of this by selecting **Output > Format List View**. This is only available when the list view is selected for the current prediction.

This dialog gives you the capability to change the date and time separator characters and the field separator (the characters between the date and time, and the time and height). You can also specify whether the month is displayed as a number or 3 letter abbreviated word, and whether you

require leading zeros on the dates and time (only the hours as the minutes always use a leading zero).

The options set in this dialog box are also used when tide data is copied to the clipboard or saved into a text file (see the next section).

Saving tidal data to disk or the clipboard

Although POLTIPS•3 has a powerful and easy to use set of features, there may be times when you need to export the data into another Windows application. POLTIPS•3 gives you two ways to do this:

- save the list view to a text file on your hard disk
- copy and paste via the clipboard

Saving a file to disk

Make your prediction as normal and ensure that you have selected list view. Make any changes to the layout using the Format List View dialog, then select either **File** > **Save as Text File**, click on the save button on the toolbar or press  + .

Enter the filename and click the save button to save the prediction to disk. This can now be loaded into any Windows application that will read in a plain (ASCII) text file (e.g. notepad, Word, Excel)

Using the Clipboard

A quicker way of getting data into another application is to use the Windows clipboard. Make your prediction as normal, then select **Edit** > **Copy**, click the copy button on the toolbar  or type  + . Now simply switch to the application you want to put the tidal data into and select **paste** from the **edit** menu of that application. Provided the program supports text input, the data should appear in the application.

Tidal Statistics

From the Tidal Predictions input dialog box, you can select to have POLTIPS•3 compute some general statistics about the tide at the selected location.

Tidal Statistics for AVONMOUTH

Latitude 51°30' N Longitude 2°43' W
 Port details: Standard port
 Datum of Predictions = Chart Datum
 6.50 metres below Ordnance Datum (Newlyn)

Highest Astronomical Tide (HAT): 14.65 metres
 HAT occurs at 08:50 GMT on 21/02/2015
 Lowest Astronomical Tide (LAT): -0.21 metres
 LAT occurs at 15:05 GMT on 10/03/1997
 Maximum Tidal Range possible: 14.79 metres

Mean High Water Spring (MHWS): 12.75 metres
 Mean High Water Neap (MHWN): 9.69 metres
 Mean Low Water Neap (MLWN): 4.16 metres
 Mean Low Water Spring (MLWS): 1.09 metres
 Tide Type: 0.02 (semidiurnal)
 Shallow Water Influence: 0.08

Selected Period: 01/10/2001 to 31/10/2001
 Highest Tide in this period: 14.26 metres
 Lowest Tide in this period: 0.30 metres
 Largest Tidal Range in this period: 13.96 metres

Average Flood time: 5 hours 52 minutes
 Average Ebb time: 6 hours 32 minutes
 Quickest Flood time: 5 hours 20 minutes

Ready NUM

The information calculated is:

- **Position** – the latitude and longitude of the port (if available).
- **Port details** – usually states whether the port is a standard port (with harmonic constants) or a secondary port (based on time and height differences) with the reference standard port.
- **Datum of Predictions** – The height of Ordnance Datum relative to Chart Datum and a description of how the Ordnance Datum is defined.
- **Highest Astronomical Tide (HAT)** – the highest level the tide is likely to reach under normal meteorological conditions and the date this occurs between 1997 and 2015 (see glossary).
- **Lowest Astronomical Tide (LAT)** – the lowest level the tide is likely to reach under normal meteorological conditions and the date this occurs between 1997 and 2015 (see glossary).
- **Maximum Tidal Range possible** – the largest difference that occurs between one high water and its adjacent low water during the period 1997 to 2015.
- **Mean High Water Springs (MHWS)** – see glossary.
- **Mean High Water Neaps (MHWN)** – see glossary.
- **Mean Low Water Neaps (MLWN)** – see glossary.
- **Mean Low Water Springs (MLWS)** – see glossary.
- **Tide Type** – gives the value which indicates whether the tide is semidiurnal, diurnal or mixed (see glossary).
- **Shallow Water Influence** – like the tide type, this is a value that indicates how much shallow water effects influence the overall tide. Values greater than 0.2 indicates a port that shows unusual tidal characteristics, especially during neap tides (see glossary).

Statistics for the Selected Period

- **Highest Tide in period** – the highest level the tide reaches in the selected time period.
- **Lowest Tide in period** – the lowest level the tide reaches in the selected time period.
- **Largest Tidal Range in period** – the biggest difference that occurs between a high water and an adjacent low water in the selected time period.
- **Average Flood time** – the average time taken for the tide to ‘come in’ i.e. average time between a low water and its adjacent high water.
- **Average Ebb time** – the average time taken for the tide to ‘go out’ i.e. average time between a high water and its adjacent low water.
- **Quickest Flood time** – the fastest time that the tide ‘comes in’ in the selected time period.

Graphs of the tide

In addition to the list view and the tide table view, POLTIPS-3 can display the tide as a graph. How this graph looks depends on whether you display a high and low water prediction or an equal interval prediction.

To bring up the graph of the tide, select **Output** & **Graph** or click on the graph button on the toolbar .

The picture below shows how one month of high and low waters might look.

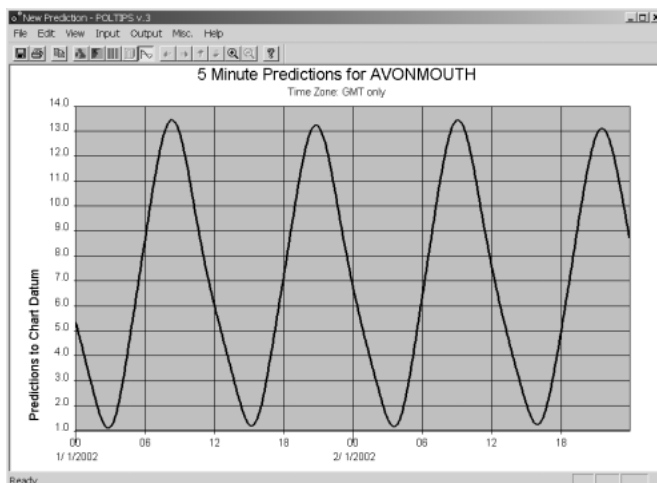

When you view the graph of a high and low water prediction, blue diamonds indicate the time (horizontal axis) and height (vertical axis) of the data. In the picture below, you can clearly see the spring-neap tidal cycle.

You can zoom in to any section on the graph by holding down the left mouse button and dragging from left to right across the graph. You will see the area you are selecting change colour, and when you release the mouse button, the selected area will be scaled to fill the window. You can also use the buttons on the toolbar   to zoom in and out.

You can scroll left and right within the limits of the prediction using the left and right arrows on the keyboard or the toolbar.

If you view the graph of an equal interval prediction, you get a continuous line showing the shape of the tide. To get an accurate graph, it is advisable to use an interval of 15 minutes or less for the prediction. Below shows how a 5 minute prediction for 2 days might look.

When viewed in list view, you get 576 values however this is much easier to grasp when you look at it as a graph.

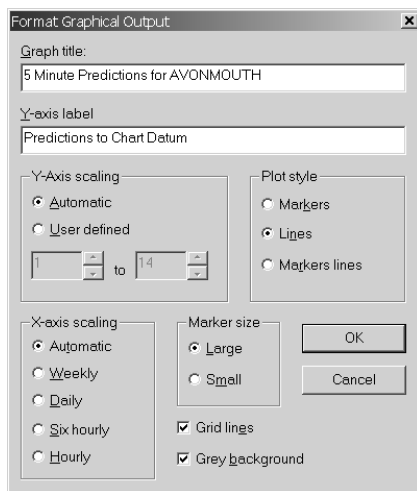

Notice that the intervals plotted on the time axis vary automatically depending on how much is displayed. When viewing a month, you only get the date of each Sunday displayed. However with 2 days in view you get every 6 hours. Zoom in further, and the graph will show every hour.

Formatting the graph view

Many of the automatic settings on the graph can be changed (for example you can remove the grey background from the graph for clearer printing). To do this, select **Output** & **Format Graph**.

From this dialog box, it is possible to change various aspects of the graph:

- the title along the top of the graph
- the text displayed along the vertical (Y) axis
- the maximum and minimum values for the vertical axis
- the interval for the time axis (default is automatic)
- the size of the markers (default is large)
- whether you want grid lines shown on the graph
- whether you want the grey background on the graph
- whether just markers, just lines or both are used to display the graph (defaults to markers only for high and low waters and lines only for interval predictions).

If the X-axis (time-axis) scaling is set to automatic, then POLTIPS•3 will select the appropriate one based on the period of time displayed on the screen.

When viewing a high and low water prediction, it is advisable only to use markers for the plot style as using lines simply joins the points together rather than showing the actual shape of the tide. You must use an equal interval prediction to get a sensible plot of the tide between the turning points.

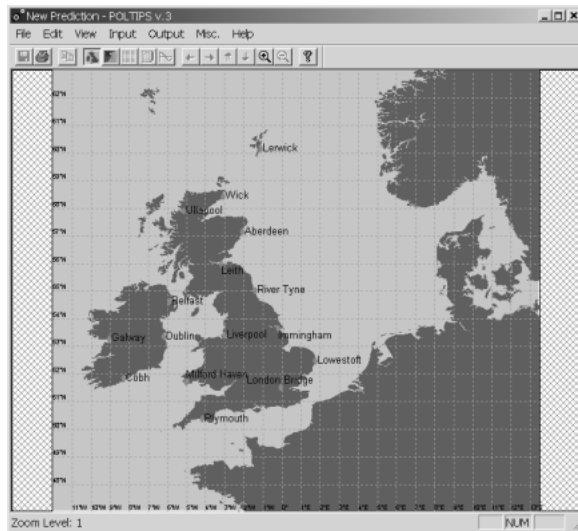

Switching between the different views

You can switch between list view, tide table view and graph view by selecting the appropriate view from the output menu or by clicking on one of the three output buttons on the toolbar   .

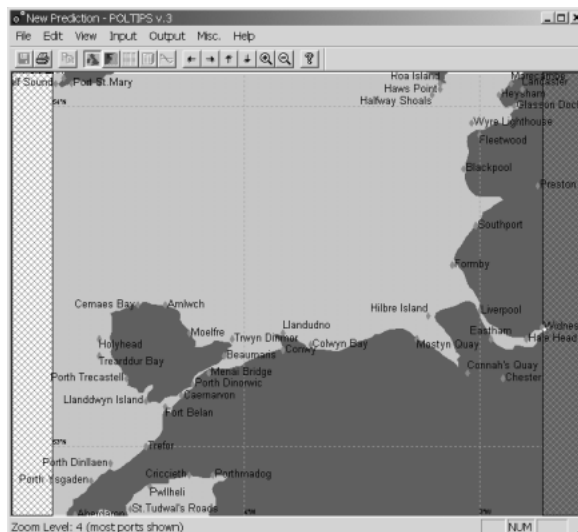

Using the map

POLTIPS•3 can display a map of the UK and the ports simply by selecting **Input & Show Map** or clicking on the toolbar button .

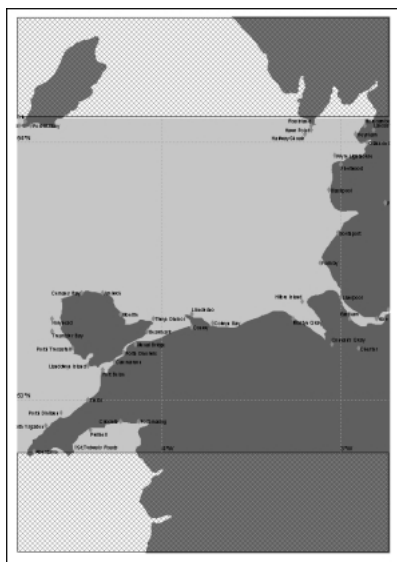

When the map is first displayed, only a selection of the ports available in POLTIPS•3 are shown. However you can zoom in to a smaller area of the coast using either the zoom buttons on the toolbar   or using the left-mouse button to drag a rectangle over the area of the map you are interested in.

As you zoom in, more ports will be displayed and the zoom level will be displayed in the status bar along the bottom of the window as “Zoom level 1” through to “Zoom level 5 (all ports shown)”

The reason for the blue shaded cross-hatching is to indicate the largest square area that can be displayed in the window. This allows consistency between the screen and printouts as the non-shaded area is the only part guaranteed to appear on both. It also remains consistent as the window is resized.

Selecting a port for prediction

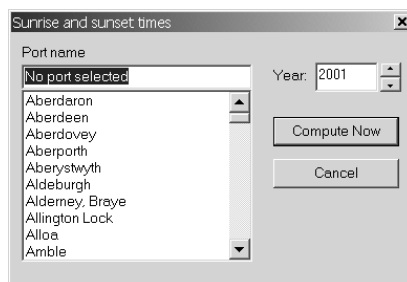

To use the map to select a port, zoom into the area so that the port name is visible and click on the small diamond next to the port name with the right mouse button. The Tidal Predictions dialog box will appear with the port name already selected.

Showing the location of a port on the map

If you have the Tidal Prediction dialog box on screen and want to locate where a particular port is, select the port from the list and click on the 'Show on Map' button. The dialog will disappear and switch to the map view with the selected port centred in the window and the zoom level set appropriately to show the surrounding ports.

Sunrise and sunset times

As POLTIPS is used by some almanac publishers, it also has the option to generate tables of sunrise and sunset times – either by selecting the port, or specifying the exact location (in latitude and longitude) and height above sea level. To bring up the dialog box,

select **Input☞Sunrise and sunset by port** to select one of the coastal locations in POLTIPS, or **Input☞Sunrise and sunset by lat,long** to specify any location.

The dialog box titled "Sunrise and sunset times" contains the following fields and controls:

- Location:**
 - Latitude:** degrees (51) and minutes (30). Radio buttons for North (selected) and South.
 - Longitude:** degrees (0) and minutes (0). Radio buttons for East (selected) and West.
- Year:** A dropdown menu showing 2001.
- Height above sea level:** A dropdown menu showing 0 (in metres).
- Buttons:** "Compute Now" and "Cancel".

Set the parameters in the dialog and click on the Compute Now button. After a couple of seconds the table giving sunrise and sunset times will be displayed. This can be scrolled in the same way as the tide table using the arrow keys or toolbar buttons.

The window "New Prediction - POLTIPS v.3" displays a table titled "Sunrise and Sunset Times" for ABERDEEN in the year 2001. The table is organized by month (January, February, March) and lists times in GMT. The status bar at the bottom shows "Ready" and a "NUM" field.

Times in GMT			ABERDEEN			Year: 2001		
January			February			March		
1	08:47	15:36	1	08:08	16:36	1	07:02	17:40

13	08:38	15:55	13	07:42	17:04	13	06:29	18:06
14	08:37	15:57	14	07:39	17:06	14	06:27	18:09
15	08:36	15:59	15	07:37	17:08	15	06:24	18:11
16	08:35	16:01	16	07:34	17:10	16	06:21	18:13
17	08:33	16:03	17	07:32	17:13	17	06:19	18:15
18	08:32	16:05	18	07:30	17:15	18	06:16	18:17
19	08:31	16:07	19	07:27	17:17	19	06:13	18:20

Note that all times for sunrise and sunset are shown in GMT only.

Custom tide table format

One of the new features to POLTIPS-3 (usually available only on the customised and UserData licence) is the ability to customise your own high and low water tide table layout. To access this, make a high and low water prediction as normal and then select **Output Custom Tide Table (HLW)**. The default layout for custom tide tables looks like the picture below.

ENGLAND, WEST COAST - AVONMOUTH
Lat 51°30' N Long 2°43' W Year : 2002

31	2257 02.39			31	2257 02.39			31	2257 02.39		

To change this layout, select **Output Format Tide Table** to bring up the dialog box shown below. As there are many settings that can be changed, they have been split across three 'tabs' called Font, Appearance and Advanced (shown below). When you make any changes to the settings, click either the 'Apply' button to see the effect of the changes without closing the dialog box, or the 'OK' button to accept the changes and close the dialog box. Once you have clicked 'Apply', you can no longer select cancel – you will need to change the settings back manually.

'Font' tab

High and Low Water Custom Tide Table Format

Font | Appearance | Advanced

Font Selection

Title	Typeface Name	Size	Bold	Italic
Title	Arial	250	<input checked="" type="checkbox"/>	<input type="checkbox"/>
Subtitle	Arial	150	<input checked="" type="checkbox"/>	<input type="checkbox"/>
Month	Arial	100	<input checked="" type="checkbox"/>	<input type="checkbox"/>
Date	Arial Narrow	165	<input checked="" type="checkbox"/>	<input type="checkbox"/>
Data	Arial Narrow	100	<input type="checkbox"/>	<input type="checkbox"/>
Footer	Arial	100	<input type="checkbox"/>	<input type="checkbox"/>

OK Cancel Apply

This tab allows you to select the font, size, weight and italic properties for each of the 6 parts of the tide table. All the fonts installed on your system should be listed in the drop-down list under typeface name.

Title refers to the top line of the tide table used for the port name.

Subtitle is the line directly below the title used to display the time zone, latitude/longitude and the year.

Month is the font settings for the month headings

Date is the settings for the date value.

Data refers to the font used for the main tidal data, as well as the 'time' and units headings, and the day of the week.

Footer is used for the datum statement and the footer text that appears at the bottom of the tide table.

In POLTIPS•3, the font size is not specified in the conventional unit of points but in its own units to allow greater precision in specifying the size. To convert from point size into POLTIPS•3 font size multiply by approximately 12.

Point Size	POLTIPS•3 Size	Point Size	POLTIPS•3 Size
20 pt	240	11 pt	132
16 pt	192	10 pt	120
14 pt	168	9 pt	108
12 pt	144	8 pt	96

The precise scaling is 12.085, but multiplying by 12 is close enough for all point sizes below 24pt.

‘Appearance’ tab

This tab allows you to adjust some of the more common properties that affect the appearance of the tide table.

Tides allows you to select whether you want just high waters, just low waters or both of them (default). You can also turn both of them off although this would not leave much in the way of data!

Show gives you the option of displaying the days of the week, the location of the port (as a latitude and longitude), the moons phases and the time and units-of-height (metres or feet) on the tide table.

It is advisable to always have the units of height shown if you intend to publish the tide table. If you turn this off, you should ensure that it is displayed elsewhere on the page.

Months per page lets you select between 1 to 4 months per page of the tide table. If you want to use larger font sizes, then you may want to select less than the default of 4 months per page (3 pages per year) to allow space for the larger fonts.

Columns per month give you the choice of 1 to 4 columns per month. The default and probably the most useful is 2 columns per page.

Relative positioning allows you to finely adjust the positioning of the data within its 'box'. The box is the allocated area on the tide table which contains the 4 tides for a particular date (one date box is shown shaded in the illustration on the right). The size of the box can vary depending on the number of columns per month and the number of months per page therefore the relative positioning values are specified as a percentage rather than an absolute measurement.

Th 1638	1.41	F 1636	2.23						
2218	12.79	2211	11.62						
4 0454	1.54	19 0432	2.48		4 0656	1.79	19 0656	1.79	10
1057	13.08	1008	11.41						

The **Date (H)**, **Time** and **Height** values are the horizontal positioning of the three values. It specifies the position of the right-hand edge of the numbers as numbers are traditionally right-aligned. In the illustration that shows the default values, the date is right justified 26% of the way across the box, the times are 60% across and the heights are 94% across.

94%		
60%		
26%		
16	0314	1.91
	0855	12.63
W	1532	1.87
	2113	12.28
100%		

Date (V) is the vertical positioning of the date. It specifies the percentage down from the top of the box for the top of the date value. This defaults to zero.

If you change the default fonts, you will probably need to adjust these values to

keep the data evenly spaced within the box. It is best to play around with the relative positioning values until you get something that looks good.

Title Lines, **Column Lines** and **Footer Lines** are used to specify if you require lines drawn to separate the titles, the columns of data and the footer. This can be set to single line, double line, dashed line or no line.

‘Advanced’ tab

High and Low Water Custom Tide Table Format

Font | Appearance | **Advanced**

Port Name
☐ Short name ☒ Long name ☐ Custom name
AVONMOUTH

Datum Information
☐ Short text ☒ Long text ☐ Custom text
Datum of Predictions = Chart Datum : 6.50 me

Time Zone Text
☒ GMT : GMT/BST
☐ Time Zone: GMT/BST

Footer text
Tides computed by POLTIPS software developed at the Proudmen Oceanographic Laboratory
Standard Footer

The standard footer text must be used for all published tide tables.

OK Cancel Apply

This contains some of the more advanced settings.

Port Name will let you select between either a short name, the long name or custom text of your choice. Examples of this:

Short name: AVONMOUTH

Long name: ENGLAND, WEST COAST – AVONMOUTH

Custom: Avonmouth (Port of Bristol)

The default is for long port name to be selected. Only the standard ports in POLTIPS•3 have a long port name. If this is selected for a secondary port, the short name will be used.

Datum Information also has the option of short text, long text and custom text. The long text (which is the default) gives the datum selected relative to the other principle datum. For example:

Short text: Datum of Predictions = Chart Datum

Long text: Datum of Predictions = Chart Datum : 6.50 metres below
Ordnance Datum (Newlyn)

Custom: CHART DATUM : 6.5m below Ordnance Datum

NOTE: Be wary of using custom datum statements in case you specify incorrect information.

Time Zone Text allows you to select between the following two formats:

Selected	Displayed if BST not selected	Displayed if BST selected
GMT ; GMT/BST	GMT	GMT/BST
Time Zone: GMT/BST	Time Zone: GMT only	Time Zone: GMT/BST

Note that the text displayed is based on whether BST was selected when the prediction was made and not on which months are displayed on screen. For example, if you predict a whole year with BST selected, and opt to display two months per page, page one which will contain January and February predictions will display GMT/BST even though BST does not start until March. This is for consistency across all pages of the tide table.

Footer Text enables you to change the line of text that appears below the datum statement at the bottom of every page. This defaults to the standard POL copyright message. Although this can be changed within the program, the condition for publication of tide tables produced by POLTIPS-3 is that it must have the standard copyright message in the footer. If you change the footer text, you will get the following warning when you click OK.

If you wish to publish tables without the standard footer text, you must first seek written permission from the Applications Group at POL.

All the settings are retained between predictions so if you set up a tide table layout you like, you can predict multiple ports or periods of time and retain the settings. If you want to use the layout at a later date, you will need to save the settings to a file on disk (see below).

Custom port name and custom datum statement changes are **not** stored between predictions as this information could potentially be wrong if a new prediction is made.

Saving your tide table settings

Once you get a tide table layout that you like, you can save your settings for use with other tide tables (for different years or locations). Select

Output  **Save Custom Tide Table Format** and specify a filename in which all the settings will be stored for later use.

When you use the program at a later date, you can calculate your tidal prediction as normal and then reload your tide table layout again using **Output**  **Select Custom Tide Table Format**.

Custom Tide Table layout files use the file extension **.ctt**.

Note that any custom datum statement or custom port name is **not** saved as part of the tide table layout. If the layout was applied to a prediction for a different port, this information would be wrong.

Using your own harmonic constants

Users of the standard version of POLTIPS are not licensed to use their own harmonic constants in the program. This feature will usually be disabled (check the title screen of the program).

PLEASE READ	<p>Do not attempt to use your own harmonic constants in the software unless you:</p> <ul style="list-style-type: none">• are comfortable editing text files on your PC• are familiar with the basic concepts of harmonic prediction.
--------------------	---

About Harmonic Constants

The basis of all tidal predictions is a set of harmonic constants for the location of interest. With these and the appropriate mathematics for calculating various astronomical parameters it is possible to predict the tide for any date future or past.

For more information on harmonic constants read the section in the Frequently Asked Questions about Tides (page 51) entitled "How can tide tables be produced so accurately?"

If you have your own sets of harmonic constants for a location, you can use POLTIPS•3 to compute tidal predictions based on these harmonics for any date and time within your licenced period. These harmonics could have been obtained from either a tidal analysis carried out for you by POL, derived from the POL Tidal Analysis Software Kit (TASK) or from some other source.

To use this feature you must have either a POLTIPS•3 customised licence or a POLTIPS•3 UserData licence. A UserData licence usually runs for 10 years.

Data Files

To incorporate your own harmonic constants into POLTIPS•3, you must modify two files in the POLTIPS directory on your hard disk. Unless you changed the default location when you installed POLTIPS, this will be **c:\Program Files\POLTIPS-3**

INDEX.DAT

If you have a **customised licence**, this file will contain a list of the ports already included in POLTIPS•3 (however your licence will restrict access to most of them). There is an example file called **indexusr.dat** which can replace index.dat that contains the additional three example ports included with POLTIPS•3.

If you have a **UserData licence**, index.dat will contain three sample ports only.

The index file contains one line per port and includes the short port name, three numbers, a descriptive piece of text, and the long port name (optional). The spacing of the information on the line is very important – see table below:

Characters	Description
1 to 31	Short port name (max 30 characters)
32	Port type: 1=standard port included by POL 2=secondary port using time/height differences 4=port created with users own constants
33 to 36	Number to indicate how to find the correct data for the port. If port type equals 4, this number is the line number in the USERCON.DAT file were the data for this port starts.
37 to 41	If port type equals 1 or 4, it indicates whether this port is prone to double high (value of 1) or double low (value of 2) waters. If unsure, leave this value as zero. If port type equals 2, it is used to indicate the reference port.
43 to 122	descriptive text – optional (however 80 spaces must be typed if no text is supplied). This is displayed in the input dialog box when a port is selected.
123 to end of line	long port name – used by default on the hourly height tide table and optionally on the custom high and low waters tide table format. (max 72 characters). Normally, only standard ports have a long name, although one could be added for any port in the index file.

As the spacing of the information must be precise, use an existing entry to line up the different pieces of information when inserting your own entry into the index file.

USERCON.DAT

This file is used to store all your own sets of harmonic constants that you will want to use in POLTIPS*3 (not the standard licence).

Each port has a minimum of 4 lines of header information and then a list of the harmonic constants (one-per-line) as shown in the example below:

```
1
SAMPLE M2 ONLY
3.000
-1.000 ODN
2.000 0.0 31
2
SAMPLE M2 AND S2
3.000
-1.000 ODN
2.000 0.0 31
1.000 0.0 36
```

The first line has a single value that indicates the number of harmonic constants for the port, the second line has the port name which in the example is "SAMPLE M2 ONLY". The third line contains the datum shift to get from mean sea level to chart datum (sometimes called Z_0). The fourth line is the height of Chart Datum relative to Ordnance Datum and the name of the Ordnance Datum used (e.g. ODN, ODL, ODB, ODD). As chart datum is normally below Ordnance Datum, this value is usually negative.

This is followed by one line per harmonic constant (i.e. if you specified there were 10 harmonic constants, there should be 10 extra lines). Each line has 3 values separated by one or more spaces. The three values required for each harmonic constant are the amplitude in metres, the phase lag in degrees and set for GMT/UT, and the harmonic constant number (see table of harmonic constants on page 61).

If you have a customised licence or a UserData licence, then there will be a sample USERCON.DAT file included giving three examples – the first two matching those shown above. The first one contains just a single M2 constant so any prediction made will look like a basic sine wave with a period of 12 hours 25 minutes. The second example includes M2 and S2, the principal lunar and solar constituents and a prediction made with this will show a simple spring-neap variation. The final example is of a real port (not disclosed as it is for sample purposes only and uses old data), and contains 17 harmonic constants.

Accessing the sample ports included with POLTIPS•3

If you have a UserData licence, the entries for these three sample ports will already be set up in the INDEX.DAT file. If you have a customised POLTIPS•3 licence, these ports are not listed in the INDEX.DAT file. To access them you will need to place an entry in the index file for them to appear in the POLTIPS•3 input dialog box, or copy the file INDEXUSR.DAT over the INDEX.DAT file.

Licence Restrictions

Users with a standard POLTIPS•3 licence cannot use this feature.

Users with a customised version of POLTIPS•3 will be able to make predictions using their own constants for the same period as their licence.

Users with a UserData licence for POLTIPS•3 will usually have a 10 year licence – this will have been specified when you purchased the software.

Showing your port on the map

If you wish for your port to appear on the map, you can insert an additional line per port into the file **latlong.txt** which is in the POLTIPS•3 directory. Use one of the existing lines in the file to line up the data as shown in the following example:

Aberdaron	52 48 N 04 43 W 4 1
Aberdeen	57 09 N 02 05 W 1 1
Aberdovey	52 32 N 04 03 W 4 1
Aberporth	52 08 N 04 33 W 4 2

In the above example, Aberdaron will be plotted on the map at 52°48' North, 4°43' West. The first number after the position indicates at what zoom level the port should be displayed (1 = always displayed, 2,3,4 means that it is only displayed as you zoom in further). The last number on the line indicates where the text is written relative to the location marker (see the example below). This is used to prevent the names of ports in close proximity overlapping.

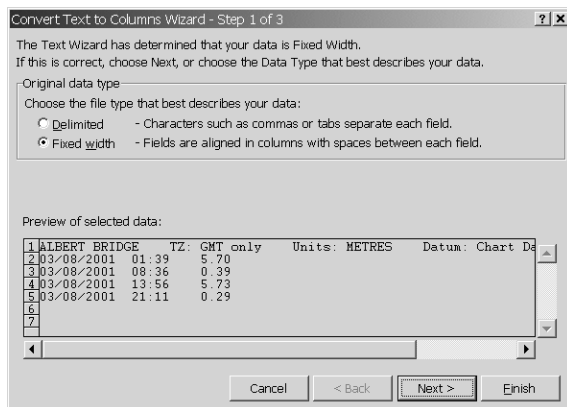

To be able to click on a port and have it automatically selected in the input dialog box, the port name in the **latlong.txt** file and the **index.dat** file must be the same (although it is not case sensitive).

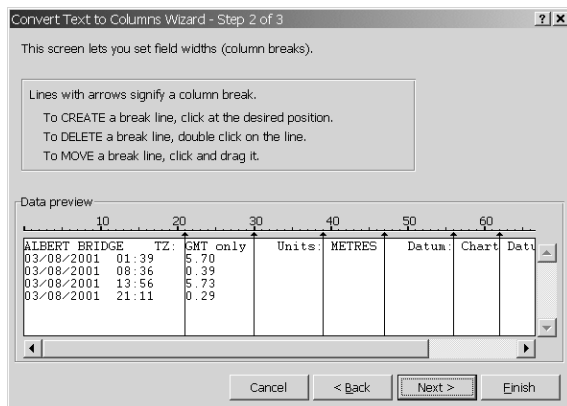

Using the data in Microsoft Excel-97

If you paste the data into Microsoft Excel, all the information will be placed in the first column of the spreadsheet. To make the data more useable you really need the date and time in one column and the levels in another column. To do this follow these steps.

1. Select column A by clicking on the letter at the top of the column.
2. From the **Data** menu, select **Text to Columns**. Step 1 of 3 of the text to columns wizard appears.
3. Select **Fixed Width** for the original data type and click the **next** button.

4. Excel will suggest some columns by putting the date and time in one and the heights in a second one. Accept these by clicking next.

5. Click finish to accept the default settings for each column.
6. You will probably need to widen column A to see the data as the date and time will not fit within the default column width.

	A	B	C	D	E	F
1	AVONMOUTH TZ: GMT only	Units: METRES	Datum: Chart Datum			
2	01/01/2002 02:49	1.11				
3	01/01/2002 08:20	13.44				
4	01/01/2002 15:13	1.19				
5	01/01/2002 20:48	13.23				
6	02/01/2002 03:33	1.16				
7	02/01/2002 09:05	13.44				
8	02/01/2002 15:57	1.25				
9	02/01/2002 21:33	13.11				
10	03/01/2002 04:15	1.31				
11	03/01/2002 09:50	13.25				
12	03/01/2002 16:38	1.41				
13	03/01/2002 22:18	12.79				
14	04/01/2002 04:54	1.54				
15	04/01/2002 10:37	12.88				
16	04/01/2002 17:18	1.66				

7. Once you have the data in this form you will be able to use many of the excel functions to derive additional statistics and information about the tide, produce frequency distributions or use the chart wizard to produce graphs.

Time and Tide

Tides are the alternating rise and fall of the surface of the seas and oceans. They are due mainly to the gravitational attraction (pull) of the moon and sun on the rotating earth. Two high and two low tides occur daily around Britain and, with average weather conditions, scientists can predict their movements with considerable accuracy.

Both moon and sun affect the tides, but since the moon is much closer to the earth (240,000 miles instead of 93,000,000 miles), it has more than twice the effect of the sun, even though it is much smaller. So, to understand tides it is best to start with the moon and the lunar tide, before looking at the effect of the sun.

As everyone knows, the moon orbits around the earth. However the earth is not fixed rigidly in space, and as the moon orbits, it attracts the earth round in a monthly orbit of its own. So the earth has a small orbit caused by the moon in addition to its annual one round the sun. It is the gravitational pull of the moon on the earth that keeps the earth in its monthly orbit.

This is just the same as when you whirl a weight round on a piece of string. It is only by constantly pulling on the string that you prevent the object from flying off. If you stop pulling completely, by letting go on the string, the object does fly off. Gravity acts in the same way as you pulling on the string, and prevents the earth from flying off.

However, unlike the string, the attractive pull of gravity gets weaker as the distance between the objects increases (and it becomes stronger, of course, the closer they get). The earth is large, so the pull of gravity on the side of the earth nearer the moon is stronger than the pull on the side of the earth farther from the moon.

The pull of the moon's gravity is just enough to keep the earth in its monthly orbit, but it is a bit stronger on the surface of the earth facing the moon (near side) and weaker on the far side. This means that on the near side, the moon tends to pull anything that's free to move towards it. In the same way, on the far side, there isn't quite enough gravitational pull, so that anything that's free to move tends to fly off, away from the moon. Of course, though land isn't free to move, the oceans are. So on the near side they are pulled into a bulge towards the moon, and on the far side, they pile up into a bulge away from the moon.

As the earth spins, different parts of the world move under the two bulges of high water and experience high tides, giving the familiar two tides a day (semi-diurnal tides) around Britain. In some parts of the world, local

effects can mean only one tide a day (diurnal tides) – for example in the South China Sea and parts of North Australia – or even no tide at all.

Between the two bulges are two troughs of low water, producing two low tides a day. The sun also creates a very similar though smaller effect (the solar tide) and it is the interaction of the lunar and solar tides that causes spring and neap tides.

Springs and Neaps

Tides change in height with low water level and high water level varying throughout the month. The tides build up to a maximum and fall to a minimum twice a month. The tides with the biggest difference between high and low water are called springs and those with the smallest are called neaps.

Spring tides happen just after every full and new moon, when the sun, moon and earth are in line. That's when lunar and solar tides line up and reinforce each other, making a bigger total tide. Neap tides occur when the moon is in the first or third quarter - when the sun, earth and moon form a right angle. The lunar high tide coincides with the solar low tide and they partly cancel out, giving a small total tide.

Because of the regular motion of the sun, moon and earth, spring tides occur roughly 36 to 48 hours after the full or new moons, and for any given location, always at roughly the same time of day. For example at Liverpool, the spring tides are generally around midnight and midday.

Not all spring tides are the same size. Springs nearest the equinoxes (21 March and 21 September - when day and night are of equal length all over the world) are slightly bigger. The explanation for this is very complex and won't be given here.

Worldly Effects

Back on earth, tides are affected by more mundane things, such as weather and the shape of the coastline. In the upper reaches of estuaries the riverbed and shape of the estuary can distort the tidal pattern, producing long flood times and short ebb times. Though the time from high tide to high tide is the same as usual - roughly 12 hours 25 minutes - low tide is not half way between them. At some places, the flood tide rises quickly after a period of low water lasting maybe four or five hours. This kind of geographical effect is very important, and because of it you should use local tide tables (available from tackle shops) when possible.

Cromer, Lowestoft and Aldeburgh are fairly close to each other on the East Anglian coast. However, high tide is hours apart at these places. This is precisely the opposite to Southend and Herne Bay, which face each

other across the mouth of the Thames. Their tides differ by only a few minutes. Without detailed geographical information, it is impossible to predict these differences, so stay with local tide tables.

Geography also affects the tidal range. Looking at tide tables for all of Britain, it's clear that the height of the tide varies around the country. For example the spring tidal range at Avonmouth is 12.2m (40ft) while at Lowestoft it's only 1.9m (6ft).

Weather which can have a profound effect on the tide, is impossible to predict when calculating tide tables. Strong winds and abnormal atmospheric pressure are two of the main causes of altered tides. For example, a strong wind blowing on to land has the effect of piling up the water, giving a higher than predicted tide.

A History of Tidal Prediction

It has long been known that there is a relationship between the movement of water in our seas and oceans, and the position of the sun and moon. Pytheas of Marseilles in the 5th Century BC was the first credited with linking the tides to the position of the moon. Pliny the Elder (AD 23-79) noted that for twice-daily tides, the maximum tidal ranges occur just after the full and new moon, and how in March and September, they were likely to be even larger still. Strabo (c54 BC to AD 24) also noticed that the tidal range in the Persian Gulf was greatest when the moon is furthest from the plane of the equator, and are small and irregular when the moon passes through the equatorial plane.

Of course not all facts about the tide were scientifically correct. Aristotle is credited with the law that no animal can die unless the tide is going out. This legend persisted for a long time, and even as recently as 1595, Parish Registers in Hartlepool recorded the phase of the tide along with the date and time of each death.

By the mid-17th century, many theories were being proposed to explain the movements of the tide. Galileo (1564-1642) stated that tides were caused by the motion of the Earth around the Sun and its own rotation on its axis inducing motions in the sea which were modified by the shape of the sea-bed. This is closer to what actually happens than Descartes (1596-1650) theory that space is filled with an invisible matter called Ether which is compressed as the moon passed overhead and pushes down on the oceans. However Kepler (1571-1630) was the first to state that the Moon exerted a gravitational attraction on the water.

In the years that followed and as the laws of planetary motion and gravitation became accepted, Kepler's idea of the tides became the most plausible.

It wasn't until Isaac Newton (1642-1727) and his law of gravitational attraction that everything fell into place. He was the first to correctly explain the spring-neap cycle, and why equinoctial tides were larger than those at other times of the year.

Now that tides were fully understood, scientists started to look for methods to accurately predict them for any date and time – future and past. Various methods have been devised for this, and all start with having a good series of observed sea levels, which are analysed to identify repeating patterns in the tide.

In 1832, Sir. John Lubbock developed a method of analysis and prediction based on relating the time and height of high and low water to the time of

lunar transit, with corrections made for lunar and solar declination and distance.

However the method generally considered to be the most accurate for most (but not all) locations is called Harmonic Analysis and Prediction. The basis for harmonic analysis is that the tide can be represented by a finite number of simple harmonic terms – each one a simple mathematical sine ‘wave’. Each constituent, either individually or in pairs, corresponds to one of the astronomical phenomena to affect the tide.

Harmonic prediction involves simply calculating these harmonic ‘waves’ for any point in time and adding the results together to get the overall tide.

Early development of Harmonic Analysis was carried out by Laplace, Lord Kelvin and George Darwin around 1910, however the most complete algebraic expansions were completed by Dr. Arthur Doodson (*left*) in 1921, then secretary of the Liverpool Tidal Institute, and from 1946 to 1960, Director at Bidston.

In 1924, the Liverpool Tidal Institute, under the directorship of Professor Proudman at Liverpool University, relocated to Bidston Observatory, and the first tide-predicting machine was installed. This machine could be ‘programmed’ with the harmonic constants for any location and used to predict the tides for any date and time. A yearly tide table took nearly a week to produce.

Five years later, the Liverpool Observatory of the Mersey Docks and Harbour Board and the Tidal Institute of the University of Liverpool amalgamated becoming the Liverpool Observatory and Tidal Institute. Dr. Doodson, now associate director, continued his ground-breaking research into new methods for the analysis of tides. Two tide-predicting machines were now in use (the only two in the British Empire), and the tidal expertise of the institute received worldwide acclaim.

During the Second World War, valuable work was carried out at the observatory. The staff worked seven days a week, from early morning to late at night, analysing and predicting tides towards the war effort. Tidal predictions were swiftly predicted for the seas around Burma, France and Holland. During these years one of the tide predicting machines was placed in a secret underground room in the Observatory grounds for security reasons. Photographic facilities were obtained, so that further copies of the predictions could be quickly provided in the event of their loss at sea.

In 1946, Dr. Doodson took over as Director at Bidston, and the Tide Prediction Service expanded. It was helped by the construction of a large 42-constituent Doodson-Légré predicting machine in 1949. This machine is still in working order at Bidston and can still predict the tide to an incredible accuracy.

The Doodson-Légré machine was the most advanced tide-prediction machine of its day. It used up to 42 harmonic constituents to predict for any location.

In 1961, shortly after the retirement of Dr Doodson, the Liverpool Observatory and Tidal Institute was renamed The University of Liverpool Tidal Institute and Observatory.

In 1969, the Institute became a component body of the Natural Environment Research Council and was renamed the Institute of Coastal Oceanography and Tides (ICOT). It was around this time that an ambitious marine research programme was embarked upon, with a significant increase in staff.

1970 saw the installation of the institute's first mainframe computer, an IBM 1130. This speeded up the computation of tide tables immensely – a yearly table now taking less than an hour to compute. The reduction of human intervention also meant that errors were less frequent so less time was spent checking the results for typing mistakes.

In 1977 the institute was renamed yet again to the Proudman Oceanographic Laboratory in honour of Professor Proudman. It continued to develop its world-renowned reputation in tidal prediction by developing new analytical methods for locations that had a reputation for being difficult to predict accurately.

By this time, ocean research had moved on to encompass the much harder to predict surge component of sea level (the change in level due to meteorological effects such as wind and atmospheric pressure). The

computer model run twice a day at the UK Meteorological Office to predict surges around the coast was developed by scientists at POL.

In 1992, the Tidal Computation and Statistics Section became known as the Applications Group and the work branched out to include offshore tidal predictions based on sophisticated computer simulations of the worlds seas and oceans.

In 1994, the first version of the POLTIPS tidal prediction package was released for the PC and could predict a yearly tide table in less than 10 minutes. The latest Windows version of the software (to which this user guide accompanies) can carry out the same task in less than 5 seconds on a typical modern PC.

It is incredible to think how far we have come over the last 80 years with the help of computing technology. And even though we know a lot about the tides, we are just beginning to fully understand the other processes that go on within our seas and oceans.

Frequently Asked Questions about Tides

The Applications Group at the Proudman Oceanographic Laboratory are often contacted by people wanting to know about tides. For this reason we compiled a Frequently Asked Questions page for the POL web site. This is included below.

1. What is a tide?

This is not as obvious as it may sound - it is not just the rise and fall of the water in our seas and oceans (tides are only one of the contributing factors in this rise and fall).

A tide is the regular and predictable movement of water caused by astronomical phenomena the way the earth, moon and sun move in relation to each other and the force of gravity. These are the values that you can see in tide tables.

Movement of water caused by meteorological effects (for example winds and atmospheric pressure changes) are called surges. These are not easily predictable and require powerful computers and sophisticated software to predict just 36 hours in advance. These are the reasons why tide table predictions do not always agree with observations. POL develops storm surge models for flood forecasting that have been run at the Met. Office since 1978. (A large positive storm surge can add a few metres to the predicted water level.)

There is also wave movement which is purely wind generated and impossible to predict accurately. Therefore statistical values are used such as significant wave height which is the average of the highest one third of waves.

2. How far ahead can the tide be predicted?

Since the tide is caused by the astronomy of the earth-moon-sun system, which is known very accurately and can be predicted well into the future, the tides can also be predicted well into the future. So if you want to plan your sailing club events for the year 2005, get in touch and (for a small fee) the Applications Group will provide you with the tide table.

When trying to predict well into the future, we have to take into account the rise in global sea level. The further into the future we try and predict, the more significant this effect can become.

3. What causes tides?

Tides are caused by the effects of gravity in the earth-moon-sun system, and the movement of those three bodies within the system. If you imagine that the earth is completely covered in water, there are two bulges of water - one towards the moon and another on the opposite side (see question 4). The rise and fall in sea level is caused by the earth rotating on its axis underneath these bulges of water. There are two tides a day because it passes under two bulges for each rotation (24 hours) (see question 7). This is called the lunar tide.

Two bulges of water are also caused by the sun, called the solar tide - and these can either reinforce or partially cancel out the lunar tide to give spring and neap tides (see question 8).

4. If gravity is always pulling towards the moon, what causes the bulge on the opposite side of the earth?

This is possibly the most common question staff at the laboratory are asked - and it could be something to do with the fact that many reference books explain it incorrectly.

Most people think the moon rotates round the earth. In reality, the earth and the moon rotate about a common centre just inside the earth's surface (indicated by the light blue dot on the diagram). At this position the two forces acting: gravity towards the moon and a rotational force away from the moon are perfectly in balance. They have to be otherwise the earth and moon would not stay in this orbit.

The 'tide-generating' force is the difference between these two forces (**not** just gravity as most people think). On the surface of the earth nearest the moon, gravity is greater than the rotational force, and so there is a net force towards the moon causing a bulge towards the moon. On the opposite side of the earth, gravity is less as it is further from the moon, so the rotational force is dominant. Hence there is a net force away from the moon. It is this that creates the second bulge away from the moon.

5. Why are the tides not the same all round the coast of Britain?

You might expect that as Britain passes under the bulge of water, time of high water would be roughly the same for all points on the coast, but it isn't. The problem is caused by the land that 'gets in the way' of the moving water. As the earth rotates, the water has to move to generate the high tides but because of the shape of coastlines and the variation in sea depth (bathymetry), there is a lag. Every location has a unique coastline and bathymetry that gives each location its unique tidal pattern.

6. How often do high tides occur?

In UK waters, approximately every 12 hours 25 minutes. You may wonder why it is not exactly 12 hours, but you must remember that the moon is also orbiting around the earth. By the time a point on the earth's surface has rotated from point x to point y (12 hours) the moon has also moved a small amount, so the earth has to rotate for an extra 25 minutes from point y to point z to be under the high water bulge.

7. Are there always two high tides a day?

No. Although most places in Britain experience approximately two tides a day (semi-diurnal) there are some places which experience what is known as a double-high water (e.g. Southampton) or double-low water (e.g. Portland). This is caused by the shape of the coastline and the bathymetry (sea depth).

Even for 'well-behaved' locations, when you look at a tide-table you will see that some days only have 3 tides. This is because the average time between high water and low water is 6 hours 12 minutes and not exactly 6 hours. Therefore on certain days, the fourth tide actually gets pushed across into the next day.

The diagrams below show a typical tidal curve for three places round the UK coast.

In some parts of the world there is only one high and one low water each day (diurnal) – for example in Karumba, Australia. In other places, it varies between semi-diurnal and diurnal as in Musay-id in the Arabian Gulf.

8. What are spring tides and neap tides?

When the earth, moon and sun are in line (during new and full moon), the bulges of water caused by the moon and sun occur in the same place on the earth's surface. The lunar tide and the solar tide are reinforcing each other - which leads to higher than average high tides, and lower than average low tides. These are called spring tides.

When the earth, moon and sun form a right angle (at 90°) the high water caused by the lunar tide coincides with the low water of the solar tide. This produces lower than average high waters and higher than average low waters which are called neap tides. They occur approximately 7 days after spring tides.

9. Why are they called spring and neap tides?

Neap means low - so that is an easy one. Spring tides can be confusing because they have nothing to do with the season. It is not exactly known where the word 'spring' comes from in this context but there are two possible origins. One possible source is a Scandinavian word meaning to 'leap up'. Another possibility is that it is related to the natural feature of a spring - which is a place where water wells up from the earth.

10. Where are the highest tides in the world?

Burncoat Head in the Bay of Fundy, Canada has an average spring tidal range of 12.9 m. The second largest tides in the world occur at Avonmouth in the Bristol Channel where the average spring range is 12.3 m. (The average spring tidal range is the average difference between high and low waters during spring tides).

11. Do the tides follow a repeated pattern?

No. There are similarities - for example every 18.6 years, we experience larger than average tides - but they never actually repeat.

12. When during a year can we expect to find the largest tides?

A day or two after the full or new moon nearest to the equinoxes. The spring equinox is usually the 21st March, and the autumn equinox, the 23rd September.

Some years have tides that are notably higher than other years. 1997 was a significant year, as will be the year 2015. For really favourable conditions - you will have to wait around until the year 3182. Even then, the tides may only be 1 or 2 cm higher than in 1997.

13. Do the planets have any affect on the tides?

The tidal force generated by a body in space is based on two things – its mass and its distance from the earth - and it is the latter of these that is far more significant. The nearest approach of Venus to earth is still more than 100 times further away than the moon. Hence the tidal force is approximately 0.000054 times that of the moon. That equates to a movement in sea level of less than a quarter of a millimetre (one hundredth of an inch). The next most significant planet is Jupiter, where the tidal force is 10 times less again. So as you can see, the effect of the planets on the tide can safely be ignored.

Even if all the planets line up such that their effects are combined, the additional force would be minuscule. During 3rd May 2000, Mercury, Venus, Mars, Jupiter and Saturn lined up with the sun and moon. At the time a rumour circulated that the collective gravitational pull would initiate earthquakes, tidal waves and volcanic eruptions, something which of course never happened.

14. How can tide tables be produced so accurately?

There are many different steps involved in obtaining the final numbers that go into a tide table. Before a tidal prediction can be made for a port, a long sequence of tidal observations for that port are needed (called a time series). This time series will include all the astronomical effects and local coastline/depth effects (which make up the tide) as well as the weather induced effects called the surge (see question 1).

As shown in questions 6 and 8, there are certain frequencies that are known to occur in the tide. Some of these are listed below:

- 12 hours (12:00:00) repeated pattern (cycle) due to the gravity of the sun.
- 12:25:14.164 cycle due to the gravity of the moon.
- 24:00 and 24:50:28.328 cycles caused by the differences in the two tidal bulges.
- 27.2122 day cycle caused by change in lunar declination (Moons angle to the Earth).
- 27.5546 day cycle caused by a regular change in the Earth-Moon distance.
- 29.5306 day cycle caused by the phases of the moon (see question 8).

Each of these cycles is called a tidal harmonic constituent and POLTIPS uses in excess of 100 of them in calculating a tide table. You can see that the length of these cycles is known very accurately (to the nearest 1000th of a second. Therefore it is easy to find them in a sequence of observations using a method called tidal analysis. Once each constituent is identified, its size (amplitude) and time of 'arrival' (phase) is stored. These two values (known as a harmonic constant) are unique for every location.

The amplitude and phase for each constituent combined with the fixed speed of that constituent allows us to predict its contribution to the overall tide forward or backward in time almost indefinitely.

Adding up the effects of all the constituents at a given location lets us predict the overall tide at any time in the future or past.

Most tide tables just list the time and height when the water is at a maximum and minimum level in each tidal cycle. This leads to approximately 2 high waters and 2 low waters every 24 hours, 50 minutes (or 4 tides a day on most days with 3 tides on every 7th or 8th day).

15. Where can I find out more information about tides?

There are many books that cover the subject of tides but the reader should be aware of inaccuracies that often exist. You should avoid books that talk about the second bulge on the far side of the earth being caused by either the moon's gravity pulling the earth away from the water or by the spin on the Earth on its axis. The daily rotation of the Earth on its axis has no effect on tides. (See page 52: If gravity is always pulling towards the moon, what causes the bulge on the opposite side of the earth?)

One excellent book on the subject:

“Tides, Surges and Mean Sea Level” – David T. Pugh. Published by John Wiley and Sons, 1987. ISBN: 0 471 91505 X

It covers the subject in immense detail but is very mathematical and rather expensive to buy.

Glossary

Datums – see section on Datums on page 19

BST – see Time Zones below

Diurnal Tides - tides that have only one high water and one low water every 24 hours, 50 minutes. This does not occur in UK waters.

Ebb Tide – the seaward tidal flow from high water to low water. The Ebb time is the time between a high water and the following low water.

Equinoctial Spring Tides – the spring tides that occur closest to the spring equinox and autumn equinox. The tidal effect due to the sun is at a maximum since the declination is zero. These usually have the largest tidal range of the year (i.e. the highest high waters and the lowest low waters).

Extreme Levels – the term used to describe levels higher than HAT or lower than LAT, caused by meteorological conditions. These can only be derived statistically and are usually quoted as the still water level that is likely to appear once every so many years.

Example of Extreme Levels for Dover

Highest Astronomical Tide	7.23m
10 year extreme level	7.74m
100 year extreme level	8.21m
1000 year extreme level	8.80m
10000 year extreme level	9.47m

Extreme level information is available from POL for many coastal and offshore locations.

Flood Tide – the landward tidal flow from low water to high water. The Flood time is the time between low water and the following high water.

GMT/UT – see Time Zones below

Harmonic Constants – the amplitude and phase of the various harmonic constituents that can be added together to calculate the overall tide. See “How can tide tables be produced so accurately” in the Frequently Asked Questions section of this manual for more details. Every location has a unique set of harmonic constants which are derived from tidal analysis of observations for that location.

Harmonic Constituents – the tide is influenced by many factors – and each one of these can be represented mathematically by one or more simple sine wave functions. Each one of these mathematical ‘waves’ is

called a harmonic constituent of the tide. There are about 150 common harmonic constituents, each directly tied in with astronomical influences on the tide

Highest and Lowest Astronomical Tide (HAT and LAT) – The Highest and Lowest Astronomical Tides are the highest and lowest levels that will normally be reached under normal meteorological conditions. To calculate this, the maximum and minimum values are taken from a continuous 19 year prediction. POLTIPS•3 uses basic knowledge of the tides to reduce the time taken to compute HAT and LAT by only predicting the tides around the spring and autumn equinoxes for the years from 1997 to 2015 (both known years of extreme tidal levels). See also the entry on **Extreme Levels**.

High and Low Waters – the times in the tidal cycle when the tide reaches its maximum and minimum height respectively. The time between successive high waters or successive low waters is about 12 hours 25 minutes for UK ports. High and low waters are collectively known as turning points as it is the point in the cycle when the tide turns from ebbing to flooding or vice versa.

Hourly Heights – a type of tidal prediction where the height of the tide is computed at an hourly interval in time and not just for the point of high and low water.

Mean High Water Neaps (MHWN) – the average level of high water during periods of neap tides.

Mean High Water Springs (MHWS) – the average level of high water during periods of spring tides.

Mean Low Water Neaps (MLWN) – the average level of low water during periods of neap tides.

Mean Low Water Springs (MLWS) – average level of low water during periods of spring tides.

Mixed Tide – tides that are neither totally semidiurnal or diurnal, however one or the other is usually predominant.

Neap Tides – tides that usually occur around the time of the first and last quarters of the moon, and have a smaller than average tidal range.

Semidiurnal Tides – tides that have two high waters and two low waters every 24 hours 50 minutes. Nearly all the tides around the UK are of this type.

Shallow Water Influence – a value that indicates how much shallow water effects influence the overall tide. See table below:

Value	Description
less than 0.1	small influence – tide should have a typically sinusoidal profile.
0.1 to 0.2	moderate influence – tide may show slightly unusual features, particularly during neap tides.
0.2 to 0.3	significant influence – tide is complex and will probably have more than 4 tides per day (see the section on locations with unusual tides on page 17).
greater than 0.3	very significant influence – tide will have a very unusual profile, possibly switching between semidiurnal and diurnal tides. Will certainly show more than 4 tides per day (see page 17).

Spring Tides – tides that usually occur one or two days after new and full moon, and have a larger than average tidal ranges.

Surges – the movement of water caused by meteorological effect (e.g. wind, atmospheric pressure changes). These are not easily predicted, requiring accurate weather forecasts and complex computer models of the seas and oceans. Tide tables do not included predictions of the surge, and explains why they may differ from what is observed. See question 1 of the Frequently Asked Questions (page 51).

Tidal Analysis – the process of extracting the amplitude and phase of each harmonic constituent from a period of tidal observations from a tide gauge. This creates a unique set of harmonic constants for that location.

Tidal Range – the difference in height between high water and an adjacent low water. As this is not constant, it is usually quoted as one of the following:

- **mean tidal range** – the average difference between high water and adjacent low water.
- **mean spring range** – the average difference between Mean High Water Springs and Mean Low Water Springs.
- **mean neap range** – the average difference between the Mean High Water Neaps and Mean Low Water Neaps.

Tide Type – specifies whether the tide is semidiurnal, diurnal or mixed. The equation below is used to calculate a value that is used to decide this.

$$\text{Value} = \frac{O_1 + K_1}{M_2 + S_2}$$

Value	Tide type
0.0 to 0.25	Semidiurnal
0.25 to 1.5	Mixed (mainly semidiurnal)
1.5 to 3	Mixed (mainly diurnal)
greater than 3	Diurnal

Time Zones – Tidal predictions are traditionally made to Greenwich Mean Time (also called Universal Time). This is the local time for all UK ports. However the UK switches to British Summer Time (BST) for 7 months of the year which is GMT+1hour. You can select BST by ticking this box on the input dialog. BST correction is only supported for high and low water predictions and **not** for interval predictions.

Turning Points – see high and low waters

Table of Harmonic Constants

No.	Name	No.	Name	No.	Name	No.	Name
